Four lecturers

- Arnaud Legrand, CNRS, INRIA MESCAL project.
- Vincent Danjean, UJF, INRIA MOAIS project.
- Derrick Kondo, INRIA, INRIA MESCAL project.
- Jean-Louis Roch, INPG, INRIA MOAIS project.

Twelve 3-hours lectures (tentative roadmap)

- Parallel Architectures [28 sep] (A. Legrand)
- High Performance Networks. How to Efficiently Program High Performance Architectures? [5,12 oct] (V. Danjean)
- Parallel algorithms: base notions [19 oct, 2 nov] (A. Legrand) Home project [2 nov]
- Practical Session [9 nov] (V. Danjean)
- Scheduling [16,23 nov] (A. Legrand)
- Cloud/Desktop Grids [30 nov] (D. Kondo)
- Parallel Algorithms: work-stealing, advanced notions [7,14 dec] (J.L. Roch)
- Student Show! [11,18 jan] (1/3 of the final mark)
- Exam [end jan] (2/3 of the final mark)

- ▶ Student Show! [11,18 jan] (1/3 of the final mark)
- ▶ Exam [end jan] (2/3 of the final mark)

▶ The content of this lecture is rather **dense** and is intended to give you a broad overview of this area.

▶ Many of the comments we do are very general and will be enlightening only if you spend time trying to figure out the whole picture.

▶ You cannot reasonably expect to have understood everything at the end of the slides.

1 hour of lecture = at least 1 hour of personal work to re-read and understand the corresponding slides

▶ At the beginning of each lecture, you will thus certainly have questions about last lecture.
If not... that's too bad for you because it will probably mean you missed some things that will prevent you from fully understanding the rest of the lecture.

▶ At the beginning of every lecture, we may ask some of you to briefly summarize what we talked about in the previous lecture.

There is a website with all the slides as well as practical information (room location, roadmap, homeworks . . .).

http://mescal.imag.fr/membres/arnaud.legrand/teaching/2009/
M2R_PC.php

If you have a question:

mailto:arnaud.legrand@imag.fr

Send me an email to this address this evening so that I can set up the mailing list.

I will then send you a very short survey to estimate your current knowledge and background on parallel computing. It is only meant to help me organizing the lectures.

What is Parallel Computing?

- **Parallel computing:** using multiple processors/cores in parallel to solve problems more quickly than with a single processor/core
- Examples of parallel machines:
  - A **Chip Multi-Processor** (CMP) contains multiple processors (called cores) on a single chip
  - A **shared memory multiprocessor** (SMP*) by connecting multiple processors to a single memory system
  - A **cluster computer** that contains multiple PCs combined together with a high speed network
  - A **grid** is a cluster of networked, loosely-coupled computers acting to perform very large tasks
- Concurrent execution comes from desire for performance; unlike the inherent concurrency in a multi-user distributed system
- * Technically, SMP stands for "Symmetric Multi-Processor"

Motivations of this first course...

- Details of machine are important for performance
  - Processor, memory system, communication (not just parallelism)
  - Before you parallelize, make sure you're getting good serial performance
  - What to expect? Use understanding of hardware limits
- There is parallelism hidden within processors
  - Pipelining, SIMD, etc
- Locality is at least as important as computation
  - Temporal: re-use of data recently used
  - Spatial: using data nearby that recently used
- Machines have memory hierarchies
  - 100s of cycles to read from DRAM (main memory)
  - Caches are fast (small) memory that optimize average case
- Can rearrange code/data to improve locality

Why Parallel Computing Now?

- Researchers have been using parallel computing for decades:
  - Mostly used in computational science and engineering
  - Problems too large to solve on one computer; use 100s or 1000s

- Many companies in the 80s/90s "bet" on parallel computing and failed
  - Computers got faster too quickly for there to be a large market

What next?

Why Parallelism (2008)?

- These arguments are no long theoretical
- All major processor vendors are producing multicore chips
  - Every machine will soon be a parallel machine
  - All programmers will be parallel programmers???
- New software and programming model
  - Want a new feature? Hide the "cost" by speeding up the code first
  - All programmers will be performance programmers???
- Some may eventually be hidden in libraries, compilers, and high level languages
  - But a lot of work is needed to get there
- Big open questions:
  - What will be the killer apps for parallel machines?
  - How should the chips be designed, and how will they be programmed?

Limit #1: Power density

Can soon put more transistors on a chip than can afford to turn on.
-- Patterson '07

Courtesy of Jean-François Méhaut
Moore's Law

- Many people interpret Moore's law as "computer gets twice as fast every 18/24 months"
  - which is not true
  - The law is about transistor density
- This wrong interpretation is no longer true
- We should have 20GHz processors right now
- And we don't!

What next?
No more Moore?

- We are used to getting faster CPUs all the time
- We are used for them to keep up with more demanding software
- Known as "Andy giveth, and Bill taketh away"
  - Andy Grove
  - Bill Gates
- It's a nice way to force people to buy computers often
- But basically, our computers get better, do more things, and it just happens automatically
- Some people call this the "performance free lunch"
- **Conventional wisdom:** "Not to worry, tomorrow's processors will have even more throughput, and anyway today's applications are increasingly throttled by factors other than CPU throughput and memory speed (e.g.,

Commodity improvements

- There are three main ways in which commodity processors keep improving:
  - Higher clock rate
  - More aggressive instruction reordering and concurrent units
  - Bigger/faster caches
- All applications can easily benefit from these improvements
  - at the cost of perhaps a recompilation
- Unfortunately, the first two are hitting their limit
  - Higher clock rate lead to high heat, power consumption
  - No more instruction reordering without compromising correctness

What next?

Is Moore's laws not true?

- Ironically, Moore's law is still true
  - The density indeed still doubles
- But its wrong interpretation is not
  - Clock rates do not doubled any more
- But we can't let this happen: computers **have** to get more powerful
- Therefore, the industry has thought of new ways to improve them: multi-core
  - Multiple CPUs on a single **chip**
- Multi-core adds another level of concurrency
  - But unlike, say multiple functional units, hard to compile for them
  - Therefore, programmers need to be trained to develop code for multi-core platforms
    - See ICS432

Limit #2: Hidden Parallelism Tapped Out

- **Superscalar (SS) designs were the state of the art; many forms of parallelism not visible to programmer**
  - **multiple instruction issue**
  - **dynamic scheduling: hardware discovers parallelism between instructions**
  - **speculative execution: look past predicted branches**
  - **non-blocking caches: multiple outstanding memory ops**
- **You may have heard of these in 61C, but you haven't needed to know about them to write software**

- **Unfortunately, these sources have been used up**

Limit #3: Speed of Light (Fundamental)

1 Tflop/s, 1
Tbyte sequential
machine

r = 0.3
mm

- Consider the 1 Tflop/s sequential machine:
  - Data must travel some distance, r, to get from memory to CPU.
  - To get 1 data element per cycle, this means 10^{12} times per second at the speed of light, $c = 3 \times 10^8$ m/s. Thus $r < c/10^{12} = 0.3$ mm.
- Now put 1 Tbyte of storage in a 0.3 mm x 0.3 mm area:
  - Each bit occupies about 1 square Angstrom, or the size of a small atom.
- No choice but parallelism

Parallelism Saves Power

- Exploit explicit parallelism for reducing power
  - Intel Slides

- **Using additional cores**
  - Increase density (= more transistors = more capacitance)
  - Can increase cores (2x) and performance (2x)
  - Or increase cores (2x), but decrease frequency (1/2): same performance at ¼ the power
- **Additional benefits**
  - Small/simple cores → more predictable performance

The Memory Bottleneck

- **The memory is a very common bottleneck that beginning programmers often don't think about**
  - When you look at code, you often pay more attention to computation
  - a[i] = b[j] + c[k]
    - The access to the 3 arrays take more time than doing an addition
    - For the code above, the memory is the bottleneck for many machines!

Memory Bottleneck: Example

- Fragment of code: a[i] = b[j] + c[k]
  - Three memory references: 2 reads, 1 write
  - One addition: can be done in one cycle
- If the memory bandwidth is 12.8GB/sec, then the rate at which the processor can access integers (4 bytes) is: 12.8*1024*1024*1024 / 4 = 3.4GHz
- The above code needs to access 3 integers
- Therefore, the rate at which the code gets its data is ~ 1.1GHz
- But the CPU could perform additions at 4GHz!
- Therefore: The memory is the bottleneck
  - And we assumed memory worked at the peak!!!
  - We ignored other possible overheads on the bus
  - In practice the gap can be around a factor 15 or higher

Locality

- The memory hierarchy is useful because of "locality"
- Temporal locality: a memory location that was referenced in the past is likely to be referenced again
- Spatial locality: a memory location next to one that was referenced in the past is likely to be referenced in the near future
- This is great, but what we write our code for performance we want our code to have the maximum amount of locality
  - The compiler can do some work for us regarding locality
  - But unfortunately not everything

Programming for Locality

- **Essentially, a programmer should keep a mental picture of the memory layout of the application, and reason about locality**
  - **When writing concurrent code on a multi-core architecture, one must also thing of which caches are shared/private**
- **This can be extremely complex, but there are a few well-known techniques**
- **The typical example is with 2-D arrays**

Moore's Law still holds but we are limited by the law of physics.

- ▶ With a single CPU, the speed of light will keep us away from TeraFlops.

- ▶ Increasing clock rate is bad (higher energy consumption, higher temperature $\rightsquigarrow$ need for cooling and thus even higher energy consumption).

- ▶ Automatic concurrency inside CPU is already there without you even noticing it. Don't expect too much on this side.

To improve performances:

- ▶ we need many different computation units

- ▶ data need to be close to computation units and well managed

- ▶ we need to expose parallelism and program with such architectures in mind.

Pipelining

- If one has a sequence of tasks to do
- If each task consists of the same n steps or *stages*
- If different steps can be done simultaneously
- Then one can have a pipelined execution of the tasks
  - e.g., for assembly line
- Goal: higher throughput (i.e., number of tasks per time unit)
Time to do 1 task	= 9
Time to do 2 tasks	= 13
Time to do 3 tasks	= 17
Time to do 4 tasks	= 21
Time to do 10 tasks	= 45
Time to do 100 tasks	= 409

Pipelining

duration of the
slowest stage

- Each step goes as fast as the slowest stage
- Therefore, the asymptotic throughput (i.e., the throughput when the number of tasks tends to infinity) is equal to:

  1 / (duration of the slowest stage)
- Therefore, in an ideal pipeline, all stages would be identical (balanced pipeline)
- Question: Can we make computer instructions all consist of the same number of stage, where all stages take the same number of clock cycles?

RISC

- Having all instructions doable in the same number of stages of the same durations is the RISC idea
- Example:
  - MIPS architecture (See THE architecture book by Patterson and Hennessy)
    - 5 stages
      - Instruction Fetch (IF)
      - Instruction Decode (ID)
      - Instruction Execute (EX)
      - Memory accesses (MEM)
      - Register Write Back (WB)
    - Each stage takes one clock cycle

**Concurrent** execution of two instructions

LD R2, 12(R3)

IF	ID	EX	MEM	WB

DADD R3, R5, R6

Pipelined Functional Units

- Although the RISC idea is attractive, some operations are just too expensive to be done in on clock cycle (during the EX stage)
- Common example: floating point operations
- Solution: implement them as a sequence of stages, so that they can be pipelined

Pipelining Today

- Pipelined functional units are common
- Fallacy: All computers today are RISC
  - RISC was of course one of the most fundamental "new" ideas in computer architectures
  - x86: Most commonly used Instruction Set Architecture today
  - Kept around for backwards compatibility reasons, because it's easy to implement (not to program for)
  - BUT: modern x86 processors decode instructions into "micro-ops", which are then executed in a RISC manner
  - New Itanium architecture uses pipelining
- Bottom line: pipelining is a pervasive (and conveniently hidden) form of concurrency in computers today
 - Take a computer architecture course to know all about it

Instruction Level Parallelism

- Instruction Level Parallelism is the set of techniques by which performance of a pipelined processor can be pushed even further
- ILP can be done by the hardware
  - Dynamic instruction scheduling
  - Dynamic branch predictions
  - Multi-issue superscalar processors
- ILP can be done by the compiler
  - Static instruction scheduling
  - Multi-issue VLIW processors
    - with multiple functional units
- Broad concept: More than one instruction is issued per clock cycle
  - e.g., 8-way multi-issue processor

MMX Extension

- Many techniques that are initially implemented in the "supercomputer" market, find their way to the mainstream
- Vector units were pioneered in supercomputers
  - Supercomputers are mostly used for scientific computing
  - Scientific computing uses tons of arrays (to represent mathematical vectors and often does regular computation with these arrays
  - Therefore, scientific code is easy to "vectorize", i.e., to generate assembly that uses the vector registers and the vector instructions
- Intel's MMX or PowerPC's AltiVec
  - MMX vector registers
    - eight 8-bit elements
    - four 16-bit elements
    - two 32-bit elements
  - AltiVec: twice the lengths
- Used for "multi-media" applications
  - image processing
  - rendering
  - ...

Vectorization Example

- Conversion from RGB to YUV

  ```
  Y = (9798*R + 19235*G + 3736*B) / 32768;
  U = (-4784*R - 9437*G + 4221*B) / 32768 + 128;
  V = (20218*R - 16941*G - 3277*B) / 32768 + 128;
  ```

- This kind of code is perfectly parallel as all pixels can be computed independently
- Can be done easily with MMX vector capabilities
  - Load 8 R values into an MMX vector register
  - Load 8 G values into an MMX vector register
  - Load 8 B values into an MMX vector register
  - Do the *, +, and / in parallel
  - Repeat

What next?

Super-threading

- Principle: the processor can execute more than one thread at a time
- Also called time-slice multithreading
- The processor is then called a *multithreaded processor*
- Requires more hardware cleverness
  - logic switches at each cycle
- Leads to less Waste
  - A thread can run during a cycle while another thread is waiting for the memory
  - Just a finer grain of interleaving
- But there is a restriction
  - Each stage of the front end or the execution core only runs instructions from ONE thread!
- Does not help with poor instruction parallelism within one thread
  - Does not reduce bubbles within a row

What next?

Multiple CPUs

- We have seen that there are many ways in which a single-threaded program can in fact achieve some amount of true concurrency in a modern processor
  - ILP, vector instructions
- On a hyper-threaded processors, a single-threaded program can also achieve some amount of true concurrency
- But there are limits to these techniques, and many systems provide increased true concurrency by using multiple CPUs

SMPs

- **Symmetric Multi-Processors**
  - often mislabeled as "Shared-Memory Processors", which has now become tolerated
- Processors are all connected to a single memory
- Symmetric: each memory cell is equally close to all processors
- Many dual-proc and quad-proc systems
  - e.g., for servers

Shared Caches

- Advantages
  - Cache placement identical to single cache
    - Only one copy of any cached block
    - Can't have different values for the same memory location
  - Good interference
    - One processor may prefetch data for another
    - Two processors can each access data within the same cache block, enabling fine-grain sharing
- Disadvantages
  - Bandwidth limitation
    - Difficult to scale to a large number of processors
    - Keeping all processors working in cache requires a lot of bandwidth
  - Size limitation
    - Building a fast large cache is expensive
  - Bad interference
    - One processor may flush another processor's data

Shared Caches

- Shared caches have known a strange evolution
- Early 1980s
  - Alliant FX-8
    - 8 processors with crossbar to interleaved 512KB cache
  - Encore & Sequent
    - first 32-bit microprocessors
    - two procs per board with a shared cache
- Then disappeared
- Only to reappear in recent MPPs
  - Cray X1: shared L3 cache
  - IBM Power 4 and Power 5: shared L2 cache
- Typical multi-proc systems do not use shared caches
- But they are common in multi-core systems

Private caches

- The main problem with private caches is that of memory consistency
- Memory consistency is jeopardized by having multiple caches
  - P1 and P2 both have a cached copy of a data item
  - P1 write to it, possibly write-through to memory
  - At this point P2 owns a stale copy
- When designing a multi-processor system, one must ensure that this cannot happen
  - By defining protocols for cache coherence

Snoopy Cache-Coherence

- The memory bus is a broadcast medium
- Caches contain information on which addresses they store
- Cache Controller "snoops" all transactions on the bus
  - A transaction is a <u>relevant transaction</u> if it involves a cache block currently contained in this cache
  - Take action to ensure coherence
    - invalidate, update, or supply value

Limits of Snoopy Coherence
Assume:

4 GHz processor

=> 16 GB/s inst BW per processor (32-bit)

=> 9.6 GB/s data BW at 30% load-store of 8-byte elements

Suppose 98% inst hit rate and 90% data hit rate

=> 320 MB/s inst BW per processor

=> 960 MB/s data BW per processor

=> 1.28 GB/s combined BW

Assuming 10 GB/s bus bandwidth

8 processors will saturate the bus

Directory-based Coherence

- Idea: Implement a "directory" that keeps track of where each copy of a data item is stored
- The directory acts as a filter
  - processors must ask permission for loading data from memory to cache
  - when an entry is changed the directory either update or invalidate cached copies
- Eliminate the overhead of broadcasting/snooping, a thus bandwidth consumption
- But is slower in terms of latency
- Used to scale up to numbers of processors that would saturate the memory bus

Example machine

- SGI Altix 3000
- A node contains up to 4 Itanium 2 processors and 32GB of memory
- Uses a mixture of snoopy and directory-based coherence
- Up to 512 processors that are cache coherent (global address space is possible for larger machines)

Sequential Consistency?

- A lot of hardware and technology to ensure cache coherence
- But the sequential consistency model may be broken anyway
  - The compiler reorders/removes code
  - Prefetch instructions cause reordering
  - The network may reorder two write messages
- Basically, a bunch of things can happen
- Virtually all commercial systems give up on the idea of maintaining strong sequential consistency

Weaker models

- The programmer must program with weaker memory models than Sequential Consistency
- Done with some rules
  - Avoid race conditions
  - Use system-provided synchronization primitives
- We will see how to program shared-memory machines
  - ICS432 is "all" about this
  - We'll just do a brief "review" in 632

Parallel Machines

- ▶ Parallel machines are expensive.
- ▶ The development tools for workstations are more mature than the contrasting proprietary solutions for parallel computers - mainly due to the non-standard nature of many parallel systems.

Workstation evolution

- ▶ Surveys show utilization of CPU cycles of desktop workstations is typically $< 10\%$.
- ▶ Performance of workstations and PCs is rapidly improving
- ▶ The communications bandwidth between workstations is increasing as new networking technologies and protocols are implemented in LANs and WANs.
- ▶ As performance grows, percent utilization will decrease even further! Organizations are reluctant to buy large supercomputers, due to the large expense and short useful life span.

Towards clusters of workstations

- ▶ Workstation clusters are easier to integrate into existing networks than special parallel computers.
- ▶ Workstation clusters are a cheap and readily available alternative to specialized High Performance Computing (HPC) platforms.
- ▶ Use of clusters of workstations as a distributed compute resource is very cost effective - incremental growth of system!!!

Definition.

A cluster is a type of parallel or distributed processing system (MIMD), which consists of a collection of interconnected stand-alone/complete computers cooperatively working together as a single, integrated computing resource.

A typical cluster

- A cluster is mainly homogeneous and is made of high performance and generally rather low cost components (PCs, Workstations, SMPs).
- Composed of a few to hundreds of machines.
- Network: Faster, closer connection than a typical LAN network; often a high speed low latency network (e.g. Myrinet, InfiniBand, Quadrix, etc.); low latency communication protocols; looser connection than SMP.

Typical usage

- Dedicated computation (rack, no screen and mouse).
- Non dedicated computation: Classical usage during the day (word, latex, mail, gcc) / HPC applications usage during the night and week-end.

Biggest clusters can be split in several parts:

- computing nodes;
- I/O nodes;
- front (interactive) node.

A few examples

Berkeley NOW (1997)
- 100 SUN UltraSPARCs.
- Myrinet 160MB/s.
- Fast Ethernet.

What next?

Icluster (2000)

▶ 225 HP iVectra PIII 733 Mhz.

▶ Fast Ethernet.

▶ 81.6 Gflops (216 nodes).

▶ top 500 (385) June 2001.

A few examples

Digitalis (2008)

▶ 34 nodes (2 xeon quad cores $\rightsquigarrow$ 272 cores) with $2 \times 8Gb$ of RAM and $2 \times 160Gb$ of HD each.

▶ Infiniband.

▶ Giga Ethernet.

DAS3: ASCI (Advanced School for Computing and Imaging),Netherlands.

- ▶ Five Linux supercomputer clusters with 550 AMD Opteron processors.
- ▶ 1TB of memory and 100TB of storage.
- ▶ Myricom Myri-10G network inside clusters.
- ▶ Clusters are interconnected by a SURFnet's multi-color optical backbone.

The concept of Grid...

The Grid: Blueprint for a New Computing Infrastructure (1998); Ian Foster, Carl Kesselman, Jack Dongarra, Fran Berman, ...

Analogy with the electric supply:

▶ You don't know where the energy comes from when you turn on your coffee machine.

▶ You don't need to know where your computations are done.
The concept of Grid (cont'd)

A grid is an infrastructure that couples:

- ▶ Computers (PCs, workstations, clusters, traditional supercomputers, and even laptops, notebooks, mobile computers, PDA, and so on);
- ▶ Software Databases (e.g., transparent access to human genome database);
- ▶ Special Instruments (e.g., radio telescope–SETI@Home Searching for Life in galaxy, Astrophysics@Swinburne for pulsars, a cave);
- ▶ People (maybe even animals who knows ?;-)

across the local/wide-area networks (enterprise, organizations, or Internet) and presents them as an unified integrated (single) resource.
It is very big and very heterogeneous!

You have probably heard of many *buzzwords*.

- Super-computing;
- Global Computing;
- Internet Computing;
- Grid Computing;
- Meta-computing;

- Web Services;
- Cloud Computing;
- Ambient computing;
- Peer-to-peer;
- Web;

Large Scale Distributed Systems

"A distributed system is a collection of independent computers that appear to the users of the system as a single computer"
Distributed Operating System. A. Tannenbaum, Prentice Hall, 1994

Tentative taxonomy

Purpose
- ▶ Information: share knowledge.
- ▶ Data: large-scale data storage.
- ▶ Computation: aggregate computing power.

Deployment model
- ▶ Not necessarily fully centralized.
- ▶ Use of caches and proxys to reduce congestion.
- ▶ Hierarchical structure is often used.
- ▶ Centralized information
Client/server

- ▶ Each peer acts both as a client and a server.
- ▶ The load is distributed over the whole network.
- ▶ Distributed information.

Peer-to-peer
Example: Web sites
Client/server; information grid

What next?

Context
- ▶ Probably the first "grid".
- ▶ Information is accessed through a URL or more often through a search engine.
- ▶ Information access is fully transparent: you generally don't know where the informations comes from (mirrors, RSS feeds,...).

Challenges   Going peer-to-peer ? Web 2.0: users also contribute.
- ▶ Social networks (Facebook).
- ▶ Recommendations (google and amazon.com).
- ▶ Crowdsourcing (wikipedia, marmiton).
- ▶ Video and photo sharing (youtube).
- ▶ Media improvement (e.g., linking picassa and google maps).
- ▶ Ease of finding relevant information and ability to tag data.

What next?

Example: Napster
Client/server; data grid

Context

▶ The first massively popular "peer-to-peer" file (MP3 only) sharing system (1999).
▶ Central servers maintain indexes of connected peers and the files they provide.
▶ Actual transactions are conducted directly between peers.

Drawbacks

▶ More client/server than truly peer-to-peer.
▶ Hence, servers have been attacked (by courts and by others to track peers offering copyrighted materials).

Context

- Removal of servers: searching can be done by flooding in unstructured overlays.
- Use of supernodes/ultrapeers (nodes with a good CPU and high bandwidth) for searching.
- Structured (hypercubes, torus, . . .) overlay networks.
- Downloading from multiple sources using hash blocks and redundancy.

Context

- Removal of servers: searching can be done by flooding in unstructured overlays.
- Use of supernodes/ultrapeers (nodes with a good CPU and high bandwidth) for searching.
- Structured (hypercubes, torus, . . .) overlay networks.
- Downloading from multiple sources using hash blocks and redundancy.

Challenges

- Ensuring anonymity.
- Ensuring good throughput and efficient multi-cast (network coding, redundancy).
- Avoiding polluted data.
- Publish-subscribe overlays for fuzzy or complex queries.
- Free-riders.

Example: Internet Computing (SETI@home)
Client/server; computation grid

Context

- Search for possible evidence of radio transmissions from extraterrestrial intelligence using data from a telescope.
- The client is generally embedded into a screensaver.
- The server distributes the work-units to volunteer clients.
- Attracting volunteers with hall of fame and teams.
- Need to cross-check the results to detect false positives.
- 5.2 million participants worldwide, over two million years of aggregate computing time since its launch in 1999. 528 TeraFLOPS (Blue Gene peaks at just over 596 TFLOPS with sustained rate of 478 TFLOPS).
- Evolved into BOINC: Berkeley Open Infrastructure for Network Computing (climate prediction, protein folding, prime number factorizing, fight cancer, Africa@home, . . .).

Example: Internet Computing (SETI@home)
Client/server; computation grid

Challenges

▶ Attract more volunteers: credits, ribbons and medals, connect with facebook.
▶ Volunteer thinking: use people's brains (intelligence, knowledge, cognition) to locate' solar dust, fossils, fold proteins.
▶ Works well for computation intensive embarrassingly parallel applications.
  ▶ Really parallel applications.
  ▶ Data intensive applications.
  ▶ Soft real-time applications.
▶ Security.
  ▶ Would you let anyone execute anything on your PC?
  ▶ Use sandboxing and virtual machines.
▶ Need to go peer-to-peer (OurGrid).

Example: Meta-computing
Client/server; computation grid

What next?

Context

▶ Principle: buy computing services (pre-installed applications + computers) on the Internet.
▶ Examples: Netsolve (UTK), NINF (Tsukuba), DIET and Scilab // (ENS Lyon/INRIA),

Challenges

▶ Data storage and distribution: avoid multiple transfers between clients and servers when executing a sequence of operations.
▶ Efficient data redistribution.
▶ Security for file transfers
▶ Peer-to-peer deployment.

Example: grid computing
Client/server; computation grid

Parallel

Within a CPU
Pipelining
ILP
Vector Units
Multi-Threading
Concurrency
Within a Box
SMP
Multi-cores
Concurrency
Across Boxes
Clusters
What next?

Context

- Principle: use a *virtual* supercomputer and execute applications on remote resources.
  "I need 200 64 bits machines with 1Tb of storage from 10:20 am to 10:40 pm."
- Need to match and locate resources, schedule applications, handle reservations, authentication, . . .
- Examples: Globus, Legion, Unicore, Condor, . . .

Challenges

- Obtaining good performances while deploying parallel codes on multiple domains.
- Communication and computation overlap. High-performance communications on heterogeneous networks.
- Need for new parallel algorithms that handle heterogeneity, hierarchy, dynamic resources,
- Complex applications ⤳ code coupling (message passing ⤳ distributed objects, components).

Summary

Deployment / Usage	Client/Server	Peer-to-peer
Data	Napster	Gnutella, Kazaa, Chord, Freenet...
Information	Web 1.0 and 1.5 Search Engines	Web 2.0
Computing	Internet Computing; Meta-computing; Grid Computing	OurGrid

A few other challenges

- ▶ Security, Authentication, Trust, Error management.
- ▶ Middleware vs. Operating System.
- ▶ Algorithms for Grid Computing.
- ▶ Software engineering.
- ▶ Social aspects (fairness, selfishness, cooperation).
- ▶ Energy saving!

Conclusion

- ▶ No real new theme but rather a combination of already existing technologies for parallel and distributed computing.
- ▶ Such combinations and ambitious goals are very hard to achieve.
- ▶ This clearly requires a pluri-disciplinary approach with a good understanding of all aspects (OS, network, middleware, security, storage, algorithms, applications, . . .).
- ▶ It would be a mistake to restrict only to computing. Research on all these aspects should be encouraged.
- ▶ It is very important to identify and discriminate new concepts from technology and fad.
- ▶ A crucial question is:

    "Should we hide the complexity or expose it?"

Tunnel Vision by Experts

- "On several recent occasions, I have been asked whether parallel computing will soon be relegated to the trash heap reserved for promising technologies that never quite make it."
  - Ken Kennedy, CRPC Directory, 1994
- "640K [of memory] ought to be enough for anybody."
  - Bill Gates, chairman of Microsoft,1981.
- "There is no reason for any individual to have a computer in their home"
  - Ken Olson, president and founder of Digital Equipment Corporation, 1977.
- "I think there is a world market for maybe five computers."
  - Thomas Watson, chairman of IBM, 1943.
